CONTROLLER FOR THE ECHELLE SPECTROGRAPH (SYSTEM NUMBER EL 653)

1

INTRODUCTION

1.1 Overall System Description

1.1.1 Optical - Mechanical

The Lick Observatory Coude Echelle Scanner System is a very high resolution spectrograph using Varo image intensifiers with an image dissector to record the data. The nature of an Echelle grating is such that the visible region of the spectrum is dispersed highly and in many different orders. To separate these orders a second dispersing device is necessary -- in our case a small standard grating.

The light from the 120-inch telescope is focused on a slit - the emergent conical beam is collimated by a mirror. The collimated beam is diffracted by the Echelle grating and deflected downward to the cross-disperser which is mounted directly underneath the collimator. This prevents stray light from ever reaching the camera. The cross disperser reflects the beam back to the Echelle grating where it becomes diffracted again. This beam is then brought to a focus by the collimator mirror on the front face of the image tube chain.

Thus the Echelle rotates about a vertical axis and the cross-disperser rotates about a horizontal axis. In order to position a desired wavelength accurately on the image tubes a positional accuracy of about 15 arc sec is necessary for the gratings. Achieving

a small amount through a gear train by a small stepping motor. Limit switches and mechanical stops prevent the table from moving too far. A potentiometer sends coarse position data back to the control box. Mounted on the motor shaft is a cam which operates a micro switch positioned by a rotary solenoid. This is used only during calibration. Each motor has a knob on one end of its shaft to permit manual movement.

CAUTION However, if the motor is moved by hand, all position data is invalid and the system must be recalibrated. (See Section 2.5)

1.2.2 Focus

The focus stage provides linear motion for the collimator focus mirror via a lead screw driven directly by a stepping motor. This stage also has limit switches, mechanical stops and a position potentiometer. The focus stage is never calibrated, as the position potentiometer is accurate enough to provide absolute position data directly.

1.3 Driver Box (EL-653-3WE)

All three stages are cabled back to the driver box mounted on an I-beam in the pit. This box couples position and limit switch data back to the control box and provides the power drivers needed to operate the motors and solenoids.

1.4 Control Box (EL-653-2LA, B, C, F)

This unit is in the slit room and enables the operator to set the position of the gratings and focus mirror. The pulses

2.2 Lamp Test

The unlabeled red button forces the digital display logic to illuminate all seven segments of each digit to test for missing or dim segments.

2.3 Meters

Meters are supplied as a coarse position indicator for the two gratings. They read a voltage derived from a position potentiometer on each stage. The meters do not have enough resolution to serve as primary position indicators, but act as a back-up to the more complex digital system. They also give an idea of stage position when power is first turned on (before the digital display has been calibrated). The focus position potentiometer is displayed as a digital number, so no meter is needed.

2.4 Display

2.4.1 Gratings

The grating position is controlled by pulses sent to the driver box. The microprocessor (MPU) counts these pulses and displays the accumulated count. The accuracy of the digital position display depends on the stepping motor responding correctly to every pulse. Each pulse rotates the motor 1.8 degrees. This movement is geared down by a factor of 2700 to give a grating rotation of 2.4 arc sec per pulse.

Calibration is required after turning on power or if a motor is turned by hand.

Calibration is advisable after hitting a limit or pressing the stop button.

2.6 ECH, CR. DISP, FOCUS

These switches are used with the thumbwheel switches to move the stages to a known position or to move a known distance.

Normal procedure is to set the thumbwheels to the new position and push the corresponding button.

The settings of the thumbwheels may be changed while the stage is moving, but if this causes the stage to change direction, a few pulses may be ignored by the motor. These few pulses will not be ignored by the displays, however, resulting in an erroneous position indication.

When a button is pressed, the motor starts at 45 pulses per second and speeds up to 350 pulses per second in about a half second. The speed remains high until the MPU senses that the motor is within 100 pulses of its final position. The motor is slowed down to avoid an abrupt halt.

To overcome the effects of any backlash which may creep into the gear trains, the motor always reaches its final position moving in the forward direction. Thus, when it has been moving in reverse, the motor will overshoot the final position by 200 pulses, stop, and come back 200 pulses in the forward direction.

3

THEORY OF OPERATION

3.1 Control Box (See drawing EL-653-2LA)

The heart of the system is the microprocessor card, EL 608. From this card, 13 of the 16 address lines go to each of two device selector (address decoder) cards, EL 630, whose outputs are used to select which of 12 input or 9 output data words are connected to the microprocessor's 8 bit bidirectional data buss.

The microprocessor (MPU) gets its input via four EL 632 "24 BIT INPUT STROBE" cards from pushbutton switches, thumbwheel switches, limit switches, multiplexer outputs and an Analog to Digital converter output. MPU outputs go through three EL 634 "24 BIT OUTPUT BUFFER" cards as digital display data, thumbwheel enables, inputs to the multiplexer, controls to the analog to digital converter, and signals to the stepping motors.

3.1.1 Microprocessor Card (EL-608-3S)

This card holds the microprocessor (MPU), G1, 3 address line buffers, G3-5, 2 bidirectional data buffers, G6-7, reset logic, G2 and G9, 256 bytes of RAM, G10, G11, 2048 bytes of EPROM, and address decoding for the RAM and EPROM, G14-16.

Program instructions reside in the EPROM while the RAM is used for any data changes such as the information being used for the displays.

3.1.2 Device Selector (EL-630-2L)

This card decodes the address lines to provide a low level on one of 16 output lines. These outputs are used to enable the I/O cards and reset flip-flops for the specified addresses. It

selector EL 630. The reset line is pulsed at power turn-on to clear all outputs.

The select lines are gated with a pulse (produced by combining $\phi 2$ and the read/write line) to latch data on the MPU buss into the selected output port. $\phi 2$ is gated with R/w to fire a one shot (G4) only during a write operation. This delays the time the latches are strobed until about 200 n sec after the rising edge of $\phi 2$. This delay is necessary to allow the data from the MPU to stabilize the buss. The output of the one shot is gated with the select inputs to determine which latch is to receive the data. In this system, the outputs are assigned hexadecimal addresses 29 through 2E and 33.

3.1.5 Display (EL-653-2LC)

The display is controlled by two data words from MPU. The word at address 2A contains two BCD numbers that determine which segments of the display digits are turned on. The word at address 2B selects which digits are enabled. Some of the bits in this word enable two digits.

When two are enabled, both halves of the word 2A contain valid segment data. But when only one digit is enabled by word 2B, only the lower 4 bits of word 2A contain valid segment data.

Word 2A is fed into two 7 segment decoder-driver cards, EL 262, that actually turn on the segment lines of the display. EL 262 also gets an input from the lamp test button which causes all segments to be turned on when pressed.

Word 2B goes first through 7406 open collector buffers before going to the LED driver, EL 451, because the input to the EL 451

with the 1v to 5v input signal and is of such a magnitude to cancel a one volt input. This accomplishes the 1v offset. The feedback resistor sets the gain as required to produce a 10 volt output with a maximum (nominal 5v) input which is different in each stage. The Echelle and Cross disperser meters are driven from the outputs of G2 and G3B to serve as coarse position indicators.

The output of the offset and gainsetting op amps are sent to an analog switch where one is selected (by inputs J, K and L) to be inverted and passed on to the ADC's analog input.

The ADC's other input is a positive logic pulse called START (conversion) from the most significant bit of word 33 which initiates the conversion process at its falling edge. The START is also wired to the input strobe, word 31, so the MPU can see that the START is really there.

The ADC output called END OF CONVERSION (EOC), is reset HIGH by the rising edge of the start pulse. When the conversion is over, the EOC lines goes low, signaling the MPU that the data is ready.

The data output of the ADC is a 12 bit word arranged as 3 four bit BCD numbers. This 3 digit number is the stage position as read by the selected position pot.

For Focus, this number is displayed directly as stage position. The grating stages require more accuracy, however, so this data cannot be used directly for determining their position, although it is accurate enough for coarse position during calibrate.

3.1.7 Limit Switches (EL-653-2LD)

Each stage has a forward and a reverse limit switch that will stop motor movement in software and light an LED on the front panel. As an extra precaution, the limits gate the pulses to the motors in E1 655.

the MPU switches to its PDP-in-control mode. The data then present would be stored and FF1 cleared by the MPU.

The MPX DATA READY line is fed back to the MPX. When it is cleared, the computer knows its data has been accepted and it can put out a new data word.

When the MPU is ready to send data to the MPX, it will load up MPX bits 2-11 and begin sampling the MPX ACCEPTED DATA output of FF2. The computer will set FF2 with PULSE 2 after it has acquired the data, and the MPU, seeing FF2 go high, clears FF2 and can send a new data word if needed.

3.2 Driver Box (EL-653-3WE)

The driver box, located in the pit, contains two solenoid drivers, and three stepping motor drivers plus associated parts. The limit switches and position pots are fed from the 3 stages to the control box through this unit.

3.2.1 Solenoid Driver (EL 562)

A level applied to the input of a solenoid driver causes 12v to appear at pin M for as long as the input level lasts. An input level will also trigger the 555 O/S whose output applies a 24v pulse to pin M. The 24v pulse is needed to pull the solenoid in, but only 12v is needed to hold it in.

3.2.2 Stepping Motor Driver (EL 572)

The forward and reverse inputs are shaped by two one-shots and fed to an up-down counter, G2, whose output is decoded by G3. The 4 outputs of G3 go high sequentially, one at a time. G4 OR's 2 adjacent outputs to provide overlapping pulses to the power transistors.

3.3.2 Grating Stages (EL-653-2WB)

The grating stage motor drives a worm against a worm wheel for a reduction of 30 to 1 with a ten turn position pot coupled to the worm wheel shaft. The echelle motor's normal range is 30,000 pulses or 150 turns, so the pot will make 5 turns. The cross disperser motor has a range of 20,000 pulses or 100 turns, so its pot will make 3 1/3 turns.

The worm wheel shaft also drives a worm inside the turntable assembly to give an additional 20 to 1 reduction for a total of 2700 to 1. Thus for every step of the motor (1.8°), the table moves $.000667^{\circ}$ or 2.4 arc sec.

Beyond the normal range reached by the motors are limit switches which, when hit, interrupt the forward and reverse pulses via gates. The software looks at the limits too, and when they are hit interrupts the program. Beyond the limit switches are mechanical stops.

3.3.3 Calibration (see Sections 2.4.1 and 2.5)

Calibration is required after turning on power or if a motor is turned by hand.

Calibration is advisable after hitting a limit switch or pressing the stop button.

The MPU uses the grating stage position pots just to determine coarse position, since they are only accurate to about 10 motor steps and cannot be used directly for calibrating the displays.

Their accuracy is good enough to position a cam wheel attached to the motor shaft to a particular point $\pm 10^{\circ}$. The cam wheel has a detent into which a microswitch can fall. The MPU watches this switch

Software Diagnostics

4.3

4.3.1 To enter the test loop, press STOP and CALIBRATE. Release STOP first, then CALIBRATE.

To exit the test loop, press STOP.

4.3.2 To zero either Echelle or cross disperser displays (has no effect on grating position), enter test loop, then press ECH. or CR. DISP.

4.3.3 To display position pot data in the focus display, enter the test loop and press both FRD and REV focus push buttons. The position pot data displayed is determined by the right-most digit of the Echelle thumbwheel. The focus pot is selected by zero. 2 selects the Echelle pot, and 4 selects the cross disperser pot.

4.3.4 The following section will be included when the Multiplexer software is added.

To find out how much noise is on a pot signal, enter the test loop, press both FRD and REV focus push buttons, then press ECH, CR. DISP. or FOC for their respective pots. The program continuously samples the pot voltage and remembers the lowest and highest value read. These values are displayed in the Echelle and cross disperser readouts respectively. The difference, and indication of relative noise, is displayed in the focus readout.

To select another pot signal, simply press ECH, CR. DISP, or FOC, whichever is desired. All 3 displays can be zeroed by pressing both FRD and REV focus buttons.

(A1)

SPECIFICATIONS

RESOLUTION: GRATINGS = 2.4 ARC SEC PER STEP
 FOCUS = 0.0003125 INCHES PER STEP

CALIBRATION TIME: MINIMUM = 7 SEC
 MAXIMUM = 3 MIN 10 SEC

POWER DISSIPATION: DRIVER BOX: NO MOTORS = 17W
 ONE MOTOR = 61 W
 TWO MOTORS = 105 W

 CONTROL BOX: FULL BRIGHT DISPLAY = 50W
 FULL DIM DISPLAY = 41 W

HEAT GENERATED BY DRIVER BOX DURING A 10 HOUR NIGHT* : 600 BTU
 : 150 KGRAM-CALORIES

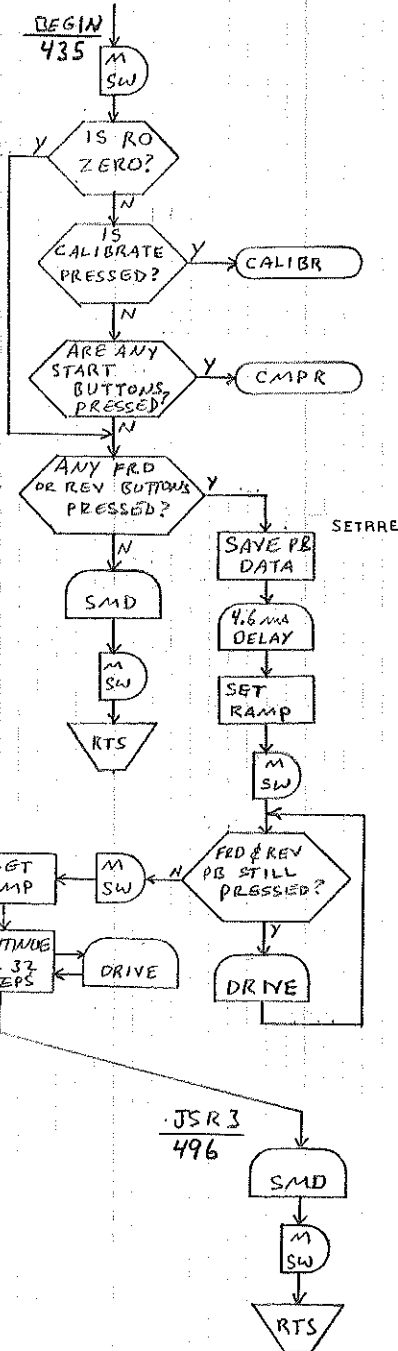

* Assumptions: Both motors run during calibration for 2 min; one motor moved for 15 sec every 10 min.

RRETST	= 71B	B-4	C-21				

START INITIALIZES FLAGS AND STACK-POINTER, CALLS RESET, AND LOADS THE CALIBRATE MAGIC NUMBER.

RESET CLEARS ALL ZERO PAGE RAM, THEN LOADS DISPLAY REGISTERS WITH A "CALIBRATION REQUIRED" CODE. THE JSR TO RDADC SETS FOCUS DISPLAY.

AGAIN AS A PRECAUTION AGAINST SUBROUTINES FAILING TO UNNEST, THERE BY FILLING THE STACK POINTER, IT IS RESET HERE. ALSO CALLS BEGIN.

BEGIN EXAMINES PUSH BUTTONS. JUMPS OFF TO CALIBRATE OR COMPARE, OR HANDLES MANUAL PB FUNCTIONS.

JSR3 MAKES ONE PASS THRU DISPLAY ROUTINE AND CLEARS STATUS WORD. SERVES AS A TERMINATOR FOR OTHER ROUTINES ALSO.

STATUS WORD OUTPUT BUFFER, R9, AND ITS SOFTWARE COMPANION, RR9, INDICATE WHERE THE PROGRAM IS OPERATING. R9 CAN BE MONITORED AS A TROUBLE-SHOOTING AID.

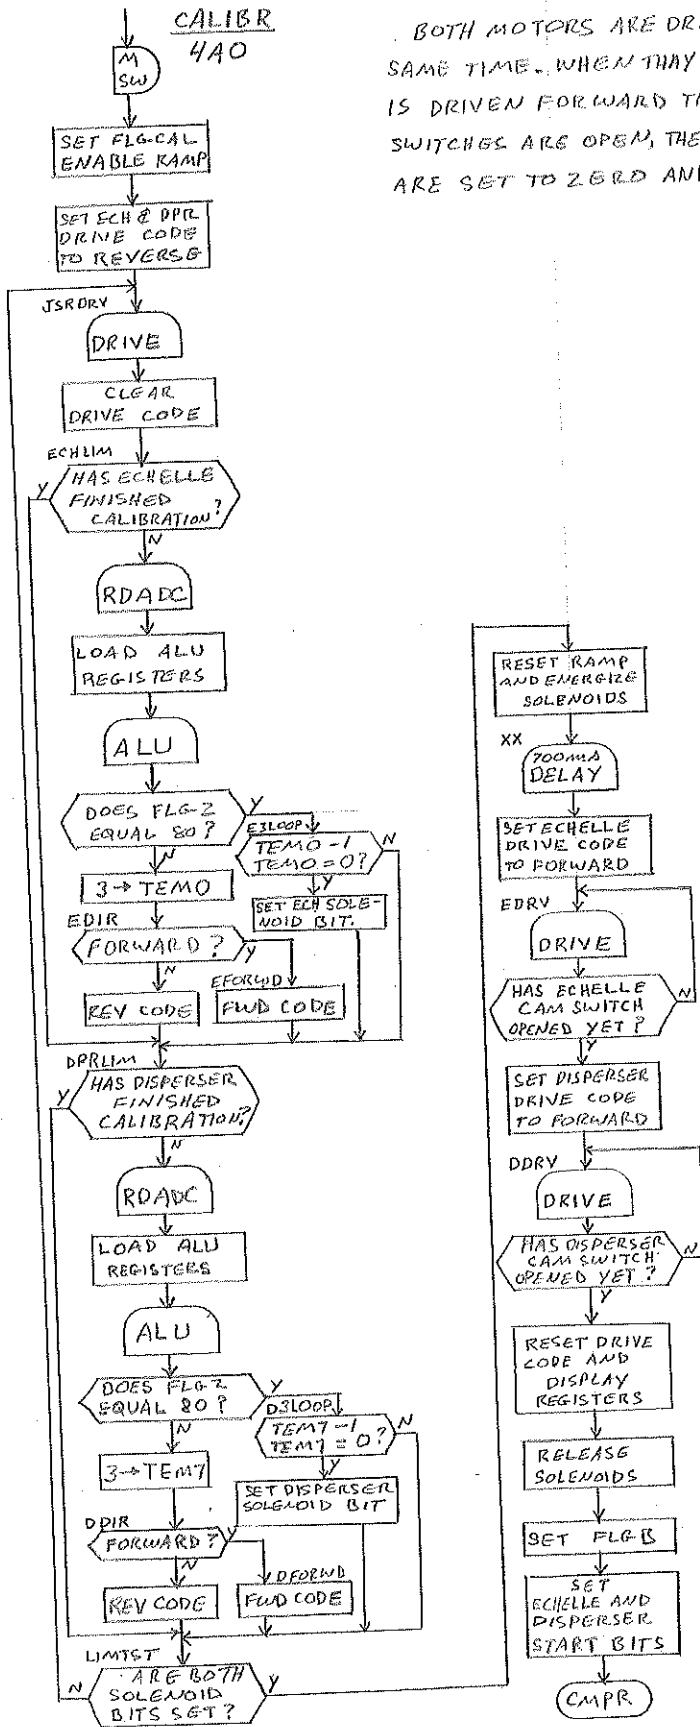

XXX = JUMP TO SUBROUTINE XXX

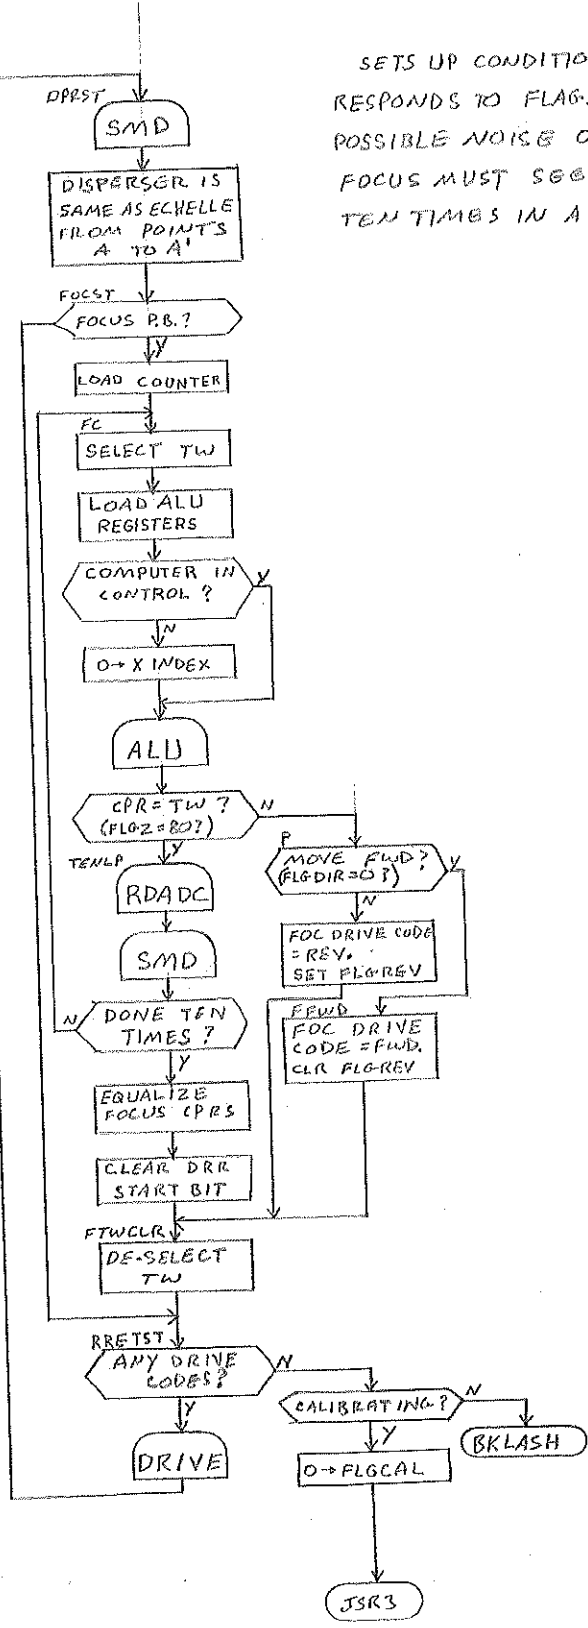

RTS = RETURN FROM SUBROUTINE

M SW = MODIFY STATUS WORD

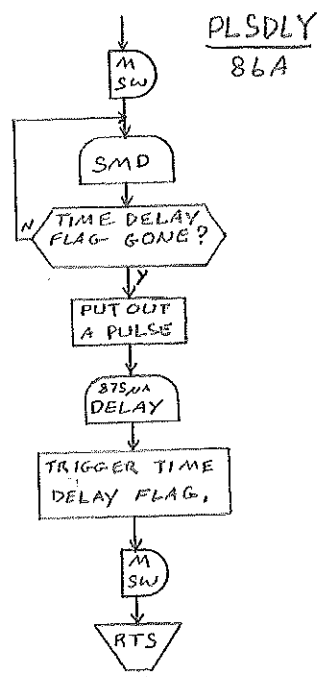

XXX = JUMP TO LOCATION XXX

BOTH MOTORS ARE DRIVEN TOWARDS A REFERENCE POINT AT THE SAME TIME. WHEN THEY'VE BOTH REACHED IT, ONE AT A TIME, EACH IS DRIVEN FORWARD TILL ITS CAM SWITCH OPENS. WHEN BOTH CAM SWITCHES ARE OPEN, THE ECHELLE AND CROSS DISPERSER DISPLAYS ARE SET TO ZERO AND CONTROL PASSES TO "CMPR".

SETS UP CONDITIONS FOR ALU. TESTS AND RESPONDS TO FLAGS SET BY ALU. DUE TO POSSIBLE NOISE ON POSITION POT SIGNALS, FOCUS MUST SEE THE SAME TW=C.P.R. DATA TEN TIMES IN A ROW.

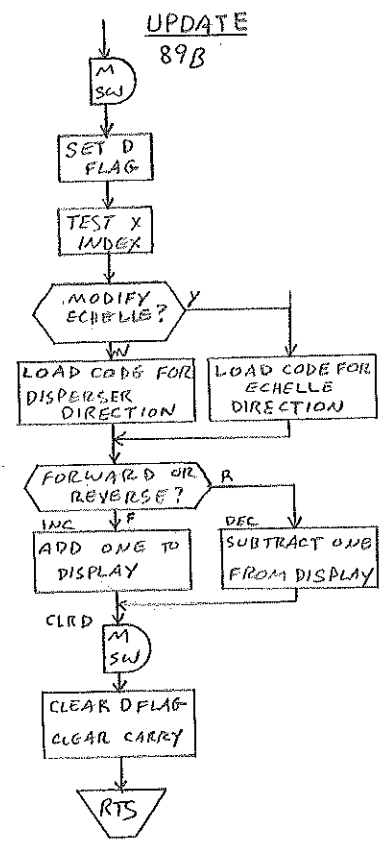

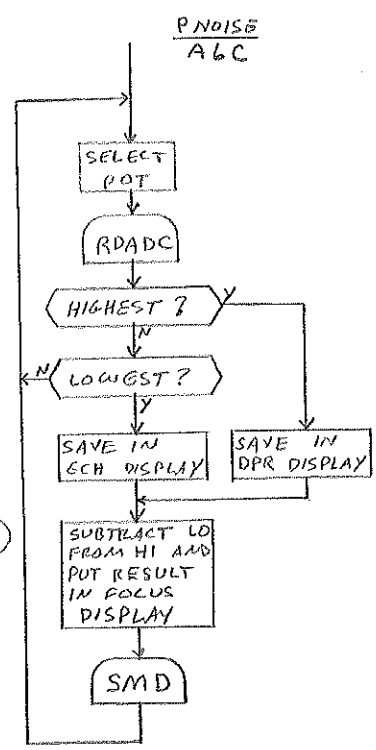

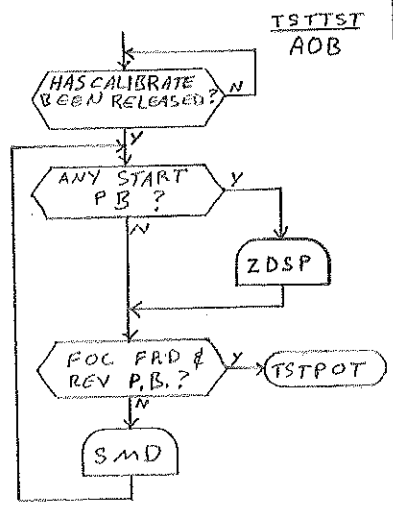

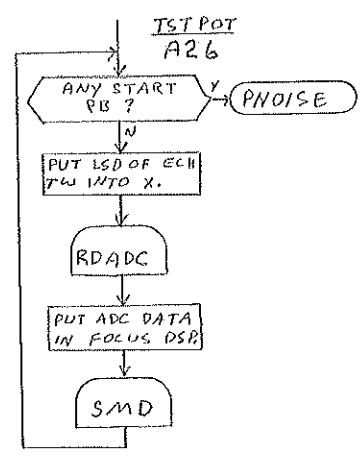

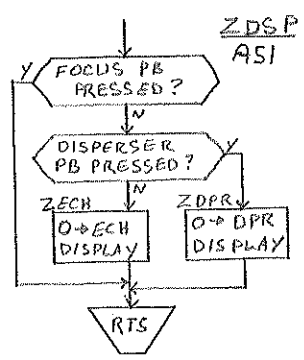

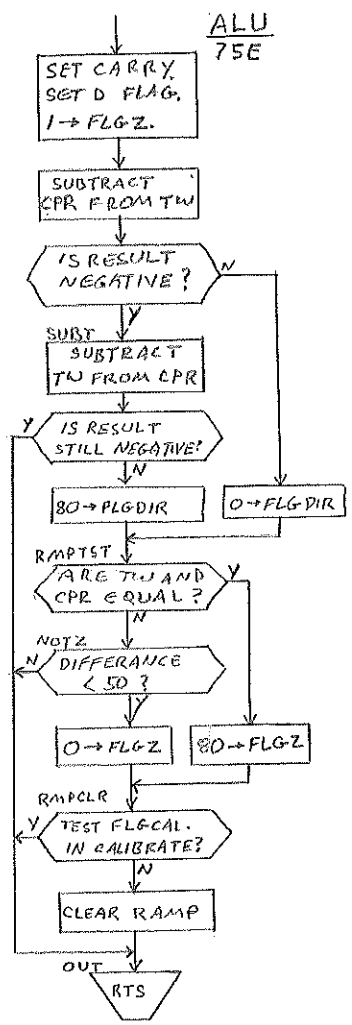

DRIVE IS MOSTLY A CALLING ROUTINE. IT CALLS THE PULSE SUBROUTINE THEN TESTS TO SEE WHICH DISPLAYS TO UPDATE. RDADC UPDATES FOCUS.

PLSDLY HAVING PREVIOUSLY SETUP A TIME DELAY FLAG, WAITS FOR IT TO TIME OUT THEN USES THE DRIVE CODE (IN REGISTER RRE) TO PUT OUT A PULSE, AND AGAIN TRIGGERS THE TIME DELAY FLAG.

UPDATE CORRECTS THE ECHELLE AND CROSS DISPERSER DISPLAYS.

DELAY A TIME WASTER TO WAIT FOR SWITCHES TO STOP BOUNCING, LEVELS TO SETTLE, ETC.

ALU DOES THE ARITHMATIC OF COMPARING TW (THUMBWHEEL) AND CPR (CURRENT POSITION REGISTER) VALUES, AND SETS DIRECTION AND MAGNITUDE FLAGS.

TSTTST REDEFINES SWITCHES FOR RUNNING TEST ROUTINES.

ZDSP PUTS ZERO INTO ECHELLE OR CROSS DISPERSER DISPLAY, WHICHEVER START BUTTON IS PRESSED. IGNORES FOC PB.

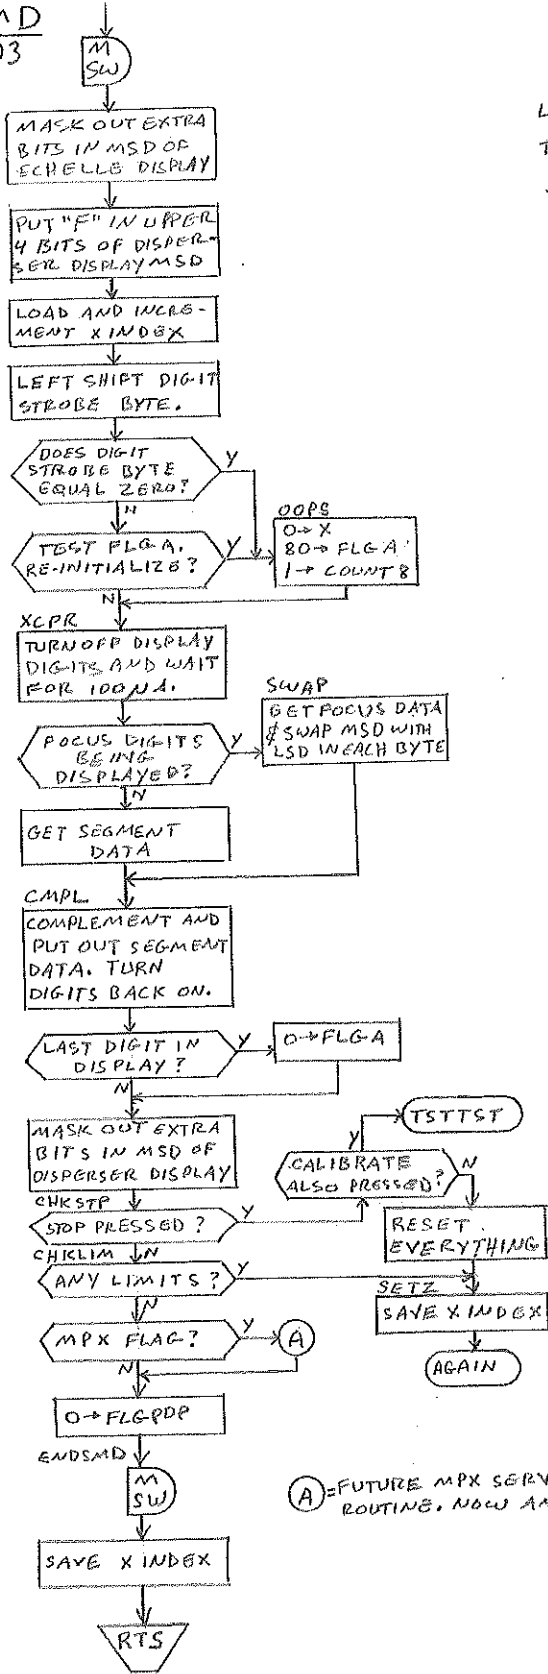

TSTPOT REDEFINES START P.B.'s FOR "PNOISE". DISPLAYS SELECTED POSITION POT VALUE IN FOC DISPLAY.

PNOISE NOT WRITTEN YET. WILL PROVIDE A RELATIVE INDICATION OF THE AMOUNT OF NOISE PRESENT ON POSITION POT SIGNAL VOLTAGE

SMD
903

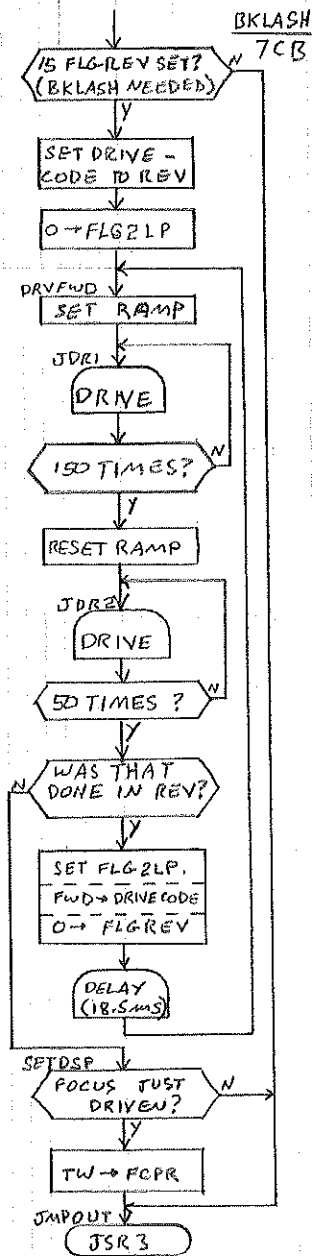

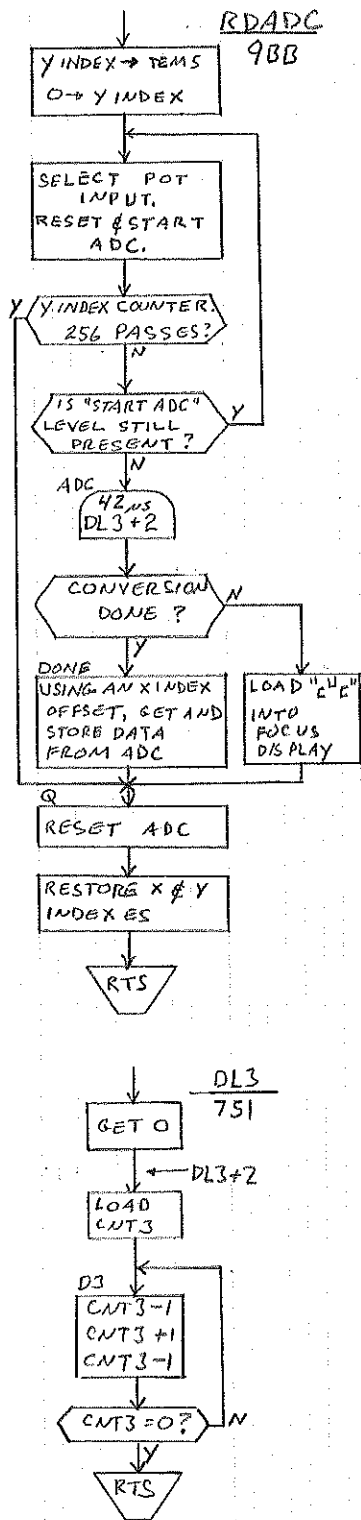

(B-7)

HERE THE DISPLAY IS OPERATED, THE STOP BUTTON, LIMIT SWITCHES, AND MULTIPLEXER FLAG- ARE TESTED. IF THE STOP AND CALIBRATE ARE BOTH DETECTED, THE PROGRAM GOES OFF TO MAINTENANCE ROUTINES.

(A) = FUTURE MPX SERVICE ROUTINE. NOW AN RTS

B-8

RDADC READS POSITION POT DATA FROM THE ADC.

DL3 GENERAL PURPOSE DELAY LOOP

BKLASH TO REMOVE ANY MECHANICAL BACKLASH, THE MOTOR CONTINUES TO GO REVERSE FOR 200 STEPS. THEN IT GOES FORWARD 200 STEPS. THUS, THE FINAL POSITION ALWAYS IS REACHED BY MOVING IN THE FORWARD DIRECTION.

EXPLANATION of COLUMNS

- ① Line numbers: Referred to by listings on pages C41-C46.
- ② Field number: Has no meaning to the actual program. Used only by the PDP-8 during assembly.
- ③ Address location in RAM or EPROM.
- ④ Data value or instruction code.
- ⑤ Mnemonics or location labels.

Columns 3 and 4 are all Hexadecimal.

In column 5, numbers preceded by "#" are Hexadecimal. All others are Octal.

FROM LOADING INSTRUCTIONS

(Computer responses are underlined. Comments are in parenthesis.)

(The PDP-8/I is used with OS/8 to edit and assemble programs for the Echelle system. A PROM programmer that operates from the PDP-8/I through multiplexer 3 is used to load OS/8 Binary files into 1Kx8 EPROMs (type 2708), which are then plugged into a Microprocessor board.)

(The ASCII source files must be assembled into a BINARY file first.)
(These source files can be found on an Archive tape.
See the Lick Programmer for a copy)

*
(Turn from programmer power off, "program inhibit" on, ground yourself and insert a PROM with pin one up. Turn power on and proceed.)

.R ABSLDR

*PROM.SV/I

(Hit "return")

*ECH/G=16426\$

(Hit "ESC", NOT "\$")

1ST CORE 2(000) OR 4(000)?2

PROM (270)4 OR (270)8 ?8

(The number of unprogrammed locations will be displayed in the PDP-8's MQ register. When the errors appear, turn "program inhibit" off. In a few seconds, the errors will all be gone. Wait for another 60 sec, then turn "program inhibit" on and hit CONTROL/C on the keyboard.)
(Turn programmer power off, ground yourself, and carefully remove the PROM. Insert a new PROM, and turn power back on. Proceed for the second PROM as for the first, noting that the response to "1ST CORE 2(000) OR 4(000)?" is "4" not "2".)
